Outline

Situation: Categorical analogue to dependent samples tests/models for continuous data.

"Matched pairs" are two samples that are statistically dependent.

- 1. Two samples have the same respondents/individuals. e.g.,
 - Same individuals respond to 2 questions.
 - Same individuals respond to 1 question at two time points. "Panel data".
- 2. The two samples are matched, a natural pairing. e.g.,
 - Ask a husband and wife the same question.
 - Have 2 people rate the same object/individual.
 - Education or occupation of parent and child. "Mobility tables".

Frequently matched pairs data yield Square Tables.

C.J. Anderson (Illinois)

Models for Matched Pairs (Models for Square Tables)

Cell telephone Data

Data from case-crossover study using non-injury car accident (collision) data from Toronto (July 1994 – August 1995). Each individual acts as their our control.

		during the		
		control interval		
		yes	no	total
during the	yes	13	157	170
hazard interval	no	24	505	529
	total	37	662	699

- ► Hazard interval is the 10 minute period prior to accident.
- Control interval is the 10 minute period at the same time of the accident but on the day before.

170/699 = .24 versus 37/699 = .05

C.J. Anderson (Illinois)

Coleman (1964) Panel data

Responses to two items made by 3398 boys:

- Attitude toward the leading crowd (positive, negative).
- Self-perception of membership in the leading crowd (yes, no).

Question: Are they measuring the same thing?

		Attitude		
		positive	negative	
Membership	yes	757	496	
	no	1071	1074	

The responses were actually collected at 2 points in time. The above responses are from time 1. We could look at consistency of responses over time or whether the marginal distributions changed or not.

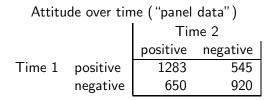

C.J. Anderson (Illinois)

Models for Matched Pairs (Models for Square Tables)

Fall 2019 8.1/48

A Mobility Table

Migration data comparing the region of residence in the U.S. in 1980 with 1985. These data are from the US Bureau of the Census (Agresti, 1990).

Residence	Residence in 1985					
in 1980	NorthEast	Midwest	South	West	Total	
NorthEast	11,607	100	366	124	12,197	
Midwest	87	13,677	515	302	14,581	
South	172	225	17,819	270	18,486	
West	63	176	286	10,192	10,717	
Total	11,929	14,178	18,986	10,888	55,981	

C.J. Anderson (Illinois)

Models for Matched Pairs (Models for Square Tables)

Methods for Square Tables

Many of the models for matched pairs data use methodology for structurally incomplete tables.

Type of analyses/models that may be warranted when studying matched pairs data:

- 1. Compare the margins of the table (dependent proportions).
 - Marginal homogeneity.
 - McNemar's test.
 - Estimating the difference between proportions (& confidence intervals for them).
- 2. For binary responses, logistic regression (for matched pairs).
 - McNemar's test.
 - Logit model with subject specific effects.
- 3. Log-linear models for comparing margins.
 - Conditional likelihood ratio test (symmetry minus quasi-symmetry).
- Measuring agreement between 2 judges/observers who rate common set of simuli/subjects/individuals.
 - Quasi-independence.
 - Cohen's Kappa
- 5. Evaluating preferences between pairs of treatments.
 - BTL model

Comparing Dependent Proportions

Cellular telephone call

		during the			
		control interval			
		yes	no	total	
during the	yes	13	157	170	
hazard interval	no	24	505	529	
	total	37	662	699	

Question: Is the probability of a car accident larger when the driver uses a cell-phone than when the driver is not using a phone? This is the same as asking whether the margins of the table the same?

Compare: 170/699 = .24 and 37/699 = .05or Difference in proportions: .24 - .05 = .19

Problem: These proportions are statistically dependent.>>><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th><</th<

Cell counts (observed data)			In terms of probabilities,			
<i>n</i> ₁₁	<i>n</i> ₁₂	<i>n</i> ₁₊		π_{11}	$\pi_{12} \\ \pi_{22}$	π_{1+}
<i>n</i> ₂₁	<i>n</i> ₂₂	<i>n</i> ₂₊	\longrightarrow	π_{21}	π_{22}	π_{2+}
n_{+1}	<i>n</i> ₊₂	<i>n</i> ++		π_{+1}	π_{+2}	π_{++}

Want to know whether

$$\pi_{1+} - \pi_{+1} = 0$$

Note:

$$\pi_{1+} - \pi_{+1} = (\pi_{11} + \pi_{12}) - (\pi_{11} + \pi_{21})$$
$$= \pi_{12} - \pi_{21}$$

・ロト ・四ト ・ヨト ・ヨト

McNemar's Test for (2×2) tables

- "Marginal Homogeneity"
- "Symmetry" across the "main diagonal".

$$H_o: \pi_{1+} = \pi_{+1}$$

or equivalently $\pi_{12} - \pi_{21}$

- Define $n^* = n_{12} + n_{21}$.
- Consider the binomial variable with n* trials that has it's two possible outcomes cells (1,2) and (2,1) in the (2 × 2) table.
- ▶ If H_o is true, then
 - Expect $n_{12} \sim n_{21}$.
 - Probability of cell (1,2) equals .5, and Probability of cell (2,1) equals .5.

C.J. Anderson (Illinois)

Models for Matched Pairs (Models for Square Tables)

Fall 2019 13.1/48

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ ののの

McNemar's Test (continued)

For "small" n^* , just compute the exact probability (*p*-value). For "large" n^* ($n^* > 10$), use the normal approximation:

$$z = \frac{n_{12} - .5n^*}{\sqrt{n^*(.5)(.5)}} = \frac{n_{12} - n_{21}}{\sqrt{n_{12} + n_{21}}}$$

where

• $.5n^* = \text{expected count (mean) for the (1,2) cell if } H_o$ is true.

• $n^*(.5)(.5) =$ the variance of the count.

Compare z to the standard normal distribution, or z^2 to the chi-square distribution with df = 1.

C.J. Anderson (Illinois)

Fall 2019 14.1

▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● の < @

Cell Phone Example

 H_o : marginal homogeneity or $\pi_{12} = \pi_{21}$ vs H_a : $\pi_{12} > \pi_{21}$ Test statistic:

$$z = \frac{157 - 24}{\sqrt{157 + 24}} = 9.89 \text{ and } P < .001$$

Estimated difference of proportions:

$$p_{1+} - p_{+1} = \frac{170}{699} - \frac{37}{699} = .24 - .05 = .19$$

To form a confidence interval for $\pi_{1+} - \pi_{+1}$, we need the standard error of the estimated difference of the proportions. . . .

C.J. Anderson (Illinois)

Fall 2019 15.1/48

イロト イポト イヨト イヨト

Cell Phone Example

The estimated variance of the difference, $\frac{p_{1+}(1-p_{1+})}{n_{++}} + \frac{p_{+1}(1-p_{+1})}{n_{++}} - 2\frac{(p_{11}p_{22}-p_{12}p_{21})}{n_{++}}$ For a $(1-\alpha)100\%$ confidence interval for $\pi_{1+} - \pi_{+1}$, $(p_{1+}-p_{+1})\pm z_{\alpha}\sqrt{\frac{p_{1+}(1-p_{1+})+p_{+1}(1-p_{+1})-2(p_{11}p_{22}-p_{12}p_{21})}{n_{++}}}$

In our example, the estimated variance of the difference is

$$\frac{.24(1-.24)+.05(1-.05)-2\left(\frac{13(505)-24(157)}{699}\right)}{699}=.0003$$

and the standard error is $\sqrt{.0003} = 0.017$. and 95% confidence interval for $(\pi_{1+} - \pi_{+1})$ is $.19 \pm 1.96(.017) \Longrightarrow (.16, .23)$, $\Xi = 300$ C.J. Anderson (Illinois) Models for Matched Pairs (Models for Square Tables) Fall 2019 16.1/48

Cell Phone Example

Notes regarding the study:

- The authors varied their choice of control interval, and arrive at the same general conclusion.
- The risk of a collision: ¹⁵⁷/₂₄ = 6.5 Drivers have a 6.5-fold increased risk of being in a collision when using a cell-phone compared to when they were not using a phone. Note: 95% Cl for risk is (4.5,10.0).
- Comparison to drunk driving:

	Risk
Blood alcohol at legal limit	4
50% alcohol above legal limit	10

17.1/48

Is there anything miss-leading in the comparison of risk while driving drunk?

Log-linear Models for Square Tables

Residence	Residence in 1985				
in 1980	NorthEast	Midwest	South	West	Total
NorthEast	11,607	100	366	124	12,197
Midwest	87	13,677	515	302	14,581
South	172	225	17,819	270	18,486
West	63	176	286	10,192	10,717
Total	11,929	14,178	18,986	10,888	55,981

Note: Relatively few people changed regions — 95% of the observations fell on the main diagonal.

Test of independence: df = (4-1)(4-1) = 9, $G^2 = 125,923$ and p < .00001.

C.J. Anderson (Illinois)

Models for Matched Pairs (Models for Square Tables)

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ ののの Fall 2019

Quasi-Independence Log-linear Model

If we disregard the diagonal, does independence hold for the off diagonal cells?

We would represent such a structure by the following log-linear model.

$$\log(\mu_{ij}) = \begin{cases} \lambda + \lambda_i^{1980} + \lambda_j^{1985} & \text{for} \quad i \neq j \\ n_{ij} & \text{for} \quad i = j \end{cases}$$

or using indicator variables,

$$\log(\mu_{ij}) = \lambda + \lambda_i^{1980} + \lambda_j^{1985} + \delta_i I(i = j)$$

where $I(i = j) = \begin{cases} 1 & \text{for } i = j \\ 0 & \text{otherwise} \end{cases}$

The δ_i parameters ensure that the diagonal cells are fit perfectly. $df = (\text{usual} df) - (\#\text{diagonals fit perfectly}) = (I_* - 1)(I_* - 1) = I_* = 0$ C.J. Anderson (Illinois) Models for Matched Pairs (Models for Square Tables) Fall 2019 22.1/48

Examples McNemar Test	Log-Linear Models	Quasi-Independence	Symmetry	Quasi–Symmetry	Marginal Homogeneity
00000000 000000000	0	00000	00000000000000	00	00000

 H_o : For people who moved (the movers), residence in 1985 is independent of region of residence in 1980.

Model	df	G^2	р
Independence	9	125,923.00	<i>p</i> < .001
Quasi-Independence	5	69.51	<i>p</i> < .001

- The quasi independence model fits much better than independence, primarily because the diagonals are fit perfectly (and this is where most of the observations are).
- Quasi independence still is missing something in the data.

C.J. Anderson (Illinois)

Models for Matched Pairs (Models for Square Tables)

Fall 2019

I

How fit Quasi-Independence

You first create (or enter) a variable that takes on a unique value for each of the diagonal cells and a common value for all of the off diagonal cells. e.g.,

$$qi = \begin{cases} 1 & i = j = 1\\ 2 & i = j = 2\\ 3 & i = j = 3\\ 4 & i = j = 4\\ 5 & i \neq j \end{cases}$$

This new variable is treated as a nominal/classifcation variable. In SAS code:...

Symmetry

This model states that

$$\mu_{ij} = \left\{ \begin{array}{ll} \mu_{ji} & \text{for} \quad i \neq j \\ n_{ii} & \text{for} \quad i = j \end{array} \right.$$

(i.e., disregard the diagonal).

This is only applicable to square tables.

Example of a perfectly symmetric table:

	1	2	3	total
1	100	20	40	160
2	20	100	30	150
3	40	30	100	170
total	160	150	170

Models for Matched Pairs (Models for Square Tables)

Fall 2019 27.1/48

イロト イポト イヨト イヨト

I

Estimation of Symmetry

MLE of μ_{ij} from the symmetry model:

$$\hat{\mu}_{ij} = \hat{\mu}_{ji} = rac{n_{ij} + n_{ji}}{2}$$

Degrees of freedom:

- There are I(I-1) off diagonal cells.
- ▶ I(I-1)/2 parameters estimated (unique fitted values).

So
$$df = (\# \text{ cells}) - (\# \text{ non-redundent parameters})$$

= $\# \text{ off diagonal cells} - \# \text{ unique parameters}$
= $I(I-1) - I(I-1)/2$
= $I(I-1)/2$

C.J. Anderson (Illinois)

Models for Matched Pairs (Models for Square Tables)

Fall 2019

イロト 不得下 イヨト イヨト 二日

Symmetry as a Log-linear Model

which will help to show what the implications of the model are for the structure in the table.

$$\log(\mu_{ij}) = \lambda + \lambda_i + \lambda_j + \lambda_{ij}$$

where $\lambda_{ij} = \lambda_{ji}$.

There are no superscripts on the main/marginal effect terms because they are the same for the rows and columns, i.e.,

$$\lambda_i = \lambda_j$$
 when $i = j$

In other words, the row and column margins are equal, i.e.,

 $\mu_{i+} = \mu_{+i}$

C.J. Anderson (Illinois)

Models for Matched Pairs (Models for Square Tables)

Fall 2019 29.1/48

The symmetry model is

- A very restrictive, because it has implications for both the association between the variables and the margins of the table. The symmetry model rarely fits data very well.
- 2. An important model because testing symmetry is often an important preliminary analysis for other analyses that require symmetric tables.

C.J. Anderson (Illinois)

Models for Matched Pairs (Models for Square Tables)

Eall 2019

イロト 不得 ト イヨト イヨト

Symmetry Example?

Example: Does the migration table exhibit symmetry? Let's first just "look" at the table?

Residence	Residence in 1985				
in 1980	NorthEast	Midwest	South	West	Total
NorthEast	11,607	100	366	124	12,197
Midwest	87	13,677	515	302	14,581
South	172	225	17,819	270	18,486
West	63	176	286	10,192	10,717
Total	11,929	14,178	18,986	10,888	55,981

Symmetry Mode: df = 4(4-1)/2 = 6, $G^2 = 243.35$, p < .001. Data do not support the symmetry hypothesis; symmetry is too simple for these data.

C.J. Anderson (Illinois)

Models for Matched Pairs (Models for Square Tables)

Fall 2019 31.1/48

Symmetry for Siskell and Ebert

			Ebert		
		Con	Mixed	Pro	
Siskel	Con	24	8	13	45
	Mixed	8	13	11	32
	Pro	10	9	64	83

Fitting Symmetry in SAS

For symmetry, you can either

- Fit the symmetry model using PROC GENMOD, as described on the following pages, or
- Use PROC FREQ with the "AGREE" option on the TABLES command. For tables where *I* > 2, this will generate the *df*, *G*² and *p*-value for the symmetry model.

Fitting the symmetry model (obtaining parameter estimates of model written as a loglinear model):

There are (at least) two ways....

Fall 2019

33.1/48

イロト イポト イヨト イヨト

I

Method I in SAS

You need to create a variable that takes on a unique value for each diagonal cell and a unique value of each pair of cells. e.g.,

$$symm = \begin{cases} 1 & i = j = 1 \\ 2 & i = j = 2 \\ 3 & i = j = 3 \\ 4 & i = j = 4 \\ 5 & (i,j) = (1,2) \text{ or } (2,1) \\ 6 & (i,j) = (1,3) \text{ or } (3,1) \\ 7 & (i,j) = (1,4) \text{ or } (4,1) \\ 8 & (i,j) = (2,3) \text{ or } (3,2) \\ 9 & (i,j) = (2,4) \text{ or } (4,2) \\ 10 & (i,j) = (3,4) \text{ or } (4,3) \end{cases}$$

 New variable is treated as a nominal variable in fitting the model.

T Method II

This method involves a little "trick" and uses standard loglinear models.

The trick is rewriting the 2-way table (with frequencies n_{ij}) as a 3-way table (with frequencies n_{iik}^*) as follows.

Create a new (conditioning) variable with 2 levels. Let's call this variable Z and index it using k, then the entries of the 3-way table equal

$$n_{ijk}^{*} = \left\{ egin{array}{cc} n_{ij} & ext{ for } k{=}1 \ n_{ji} & ext{ for } k{=}2 \end{array}
ight.$$

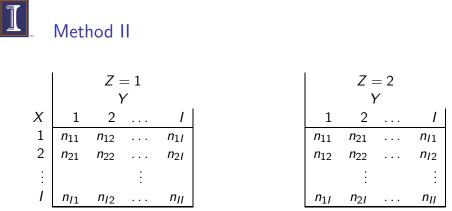

That is. . .

The symmetry model corresponds to the joint independence loglinear model (XY,Z).

C.J. Anderson (Illinois)

Models for Matched Pairs (Models for Square Tables)

38.1/48

э

Method II

The symmetry model corresponds to the joint independence loglinear model (XY,Z).

To see why this works, take a table that exhibit perfect symmetry,

$$\{n_{ij}\} = \begin{pmatrix} 100 & 20 & 40\\ 20 & 100 & 30\\ 40 & 30 & 100 \end{pmatrix}$$

Then
$$\{n_{ij1}^*\} = \begin{pmatrix} 100 & 20 & 40\\ 20 & 100 & 30\\ 40 & 30 & 100 \end{pmatrix} \text{ and } \{n_{ij2}^*\} = \begin{pmatrix} 100 & 20 & 40\\ 20 & 100 & 30\\ 40 & 30 & 100 \end{pmatrix}$$

or we can write is as Z crossed with XY

	X = 1				X = 2			<i>X</i> = 3		
Ζ	Y = 1	2	3	1	2	3	1	2	3	
1	100	20	40	20	100	30	40	30	100	
2	100	20	40	20	100	30	40	30	100	

When XY is (jointly) independent of Z, then the 2-way table of X crossed with Y is symmetric.

Note that if you use this method, you need to adjust the fit statistics and degrees of freedom. The computer gives you G^2 for a 3-way table. Every cells is counted twice instead of just once, so to get the correct G^2 and df, just divide by 2.

Quasi-Symmetry

Since symmetry is so restrictive, we can remove the restriction that the margins much be equal (i.e., "marginal homogeneity"). In other words, we will drop the requirement that the main/marginal effects for the two variables are equal. The quasi-symmetric log-linear model (for migration example) is

$$\log(\mu_{ij}) = \lambda + \lambda_i^{1980} + \lambda_j^{1985} + \lambda_{ij}$$

where $\lambda_{ii} = \lambda_{ii}$.

$$df = (\#of cell) - (\#non-redundant parameters) = I^2 - [1 + (I - 1) + (I - 1) + I(I - 1)/2] = (I - 2)(I - 1)/2$$

Fit of quasi-symmetry: df = (4-2)(4-1)/2 = 2(3)/2 = 3, $G^2 = 2.99, p = .39$ ▲□▶ ▲□▶ ▲ □▶ ▲ □▶ ▲ □ ● の < @ C.J. Anderson (Illinois) Models for Matched Pairs (Models for Square Tables) Fall 2019

1

Fitting Quasi–Symmetry

To fit the quasi-symmetry model, modify methods for fitting symmetry: Use the "symm" (symmetry) variable from fitting symmetry and add the row and column variable to the model.

```
    The modification needed for SAS
PROC GENMOD;
CLASS 1980 1985 symm;
MODEL count = 1980 1985 symm /LINK=log
DIST=poi;
    Modification for R
```

Marginal Homogeneity

Are the row and column distributions (of a square table) the same? The null hypothesis is

$$H_o: \mu_{i+} = \mu_{+i}$$

This is a simple hypothesis, but it difficult to test, because there is no way to use log-linear models to directly fit/test this model. Options:

- 1. Do not use log-linear models.
- 2. Use generalized least squares instead of maximum likelihood estimation.
- 3. Indirectly test it using log-linear models (i.e., conditional likelihood ratio test).

We'll discuss (3): a contextual/comparision test.

More about quasi-symmetry

The model:

$$\log(\mu_{ij}) = \lambda + \lambda_i^{1980} + \lambda_j^{1985} + \lambda_{ij}$$

or

$$\mu_{ij} = \exp[\lambda + \lambda_i^{1980} + \lambda_j^{1985} + \lambda_{ij}]$$

where $\lambda_{ij} = \lambda_{ji}$. Re-arranging terms in the model,

$$\frac{\mu_{ij}}{\exp[\lambda + \lambda_i^{1980} + \lambda_j^{1985}]} = \exp[\lambda_{ij}]$$

Using our parameter estimates and data, let's compute

$$\frac{n_{ij}}{\exp[\hat{\lambda} + \hat{\lambda}_i^{1980} + \hat{\lambda}_j^{1985}]} \sim \text{symetric association}$$

Summary: Relationship between Log-linear Models

- The most general (complex) model is quasi-symmetry.
- Symmetry is a special case of quasi-symmetry. i.e.,

$$\mu_{ij} = \lambda + \lambda_i^X + \lambda_j^Y + \lambda_{ij}$$

where $\lambda_{ij} = \lambda_{ji}$, and $\lambda_i^X = \lambda_i^Y$.

 Quasi-independence is a special case of quasi-symmetry. Model of quasi symmetry is

$$\mu_{ij} = \lambda + \lambda_i^X + \lambda_j^Y + \lambda_{ij}$$

where $\lambda_{ij} = \lambda_{ji}$. The model of quasi independence is

$$\mu_{ij} = \lambda + \lambda_i^X + \lambda_j^Y + \delta_i I(i=j)$$

where

$$I(i = j) = \begin{cases} 1 & \text{for } i = j \text{ (diagonals)} \\ 0 & \text{for } i \neq j \text{ (off diagonals)} \end{cases}$$

C.J. Anderson (Illinois)

Models for Matched Pairs (Models for Square Tables)

Fall 2019 47.1/48

Summary: Relationship between Log-linear Models

To see that quasi-independence is a special case of quasi-symmetry note that in the quasi-independence model, for the off diagonal cells,

$$\lambda_{ij} = \lambda_{ji} = 0$$

- Symmetry is **not** a special case of quasi-independence.
- Quasi-independence is **not** a special case of symmetry.
